NEED OF PLANNED OBSERVATIONS OF MAGNETIC STARS

To evaluate the reliability of each class of models invoked to interpret the behaviour of magnetic stars, the variation curves of magnetic field intensity, radial velocity and brightness are needed (Blanco et al. 1972).

At present about 400 stars are considered magnetic or suspected magnetic. Among these, Zeeman measurements are available for 128 stars. These stars are listed in Table I if, at least for a Zeeman measurement, the probable error is less than one third of the measure itself, otherwise they are listed in Table II. In both tables the types of available observations, for which periodic curves do exist, are indicated as follows:

H = magnetic field intensity curves

V<sub>r</sub> = radial velocity curves

l = photometric curves

W<sub>λ</sub> = spectral line intensity curves

An asterisk in the l column denotes the stars being photoelectrically observed at the Catania Observatory.

From Table I it is evident that only for a few stars magnetic field intensity, radial velocity and brightness curves are available; furthermore the various kinds of observations have been carried out at very different epochs. In the present conditions any attempt to evaluate the reliability of the available models seems to be extremely precarious.

The need of an international planning in the field of magnetic star observations (simultaneous magnetic field intensity and brightness observations) is evident.
