PHOTOELECTRIC OBSERVATIONS OF THE FLARE STAR UV Cet IN 1974, 1975

Continuous photoelectric monitoring of the flare star UV Cet has been carried out at the Stephanion Observatory ( $\lambda = -22^{\circ}49'44''$ ,  $\phi = +37^{\circ}45'15''$ ) during the years 1974, 1975 using the 30-inch Cassegrain reflector of the Department of Geodetic Astronomy, University of Thessaloniki. Observations have been made with a Johnson dual channel photoelectric photometer in the B colour of the international UBV system. The telescope and photometer will be described elsewhere. Here we mention only that the transformation of our instrumental ubv system to the international UBV system is given by the following equations:

$$\begin{aligned} V &= v_o - 0.018(b-v) + 2.297, \\ (B-V) &= 0.886 + 1.004(b-v)_o, \\ (U-B) &= -1.818 + 0.974(u-b)_o. \end{aligned}$$

The monitoring intervals in UT as well as the total monitoring time for each night are given in the Tables Ia, Ib. Any interruption of more than one minute has been noted. In the fourth column of Tables Ia, Ib the standard deviation of random noise fluctuation  $\sigma(\text{mag}) = 2.5 \log(I_o + \sigma)/I_o$  for different times (UT) of the corresponding monitoring intervals is given.

During the 41 hours of the monitoring time 23 flares were observed the characteristics of which are given in Table II. For each flare following characteristics (Andrews et al., 1969) are given: a) the date and universal time of flare maximum, b) the duration before and after the maximum ( $t_b$  and  $t_a$ , respectively), as well as the total duration of the flare, c) the value of the ratio  $(I_f - I_o)/I_o$  corresponding to flare maximum, where  $I_o$  is the intensity deflection less sky background of the quiet star and  $I_f$  is the total intensity deflection less sky background of the star plus flare, d) the integrated intensity of the flare over its

Table Ia
