The outburst of the pre-main sequence (PMS) star V1647 Ori was discovered by the amateur astronomer Jay McNeil in January 2004 (McNeil 2004). The star showed an increase of its optical brightness by around 5 mag beginning from November 2003 till February-March 2004 (Briceño et al. 2004). V1647 Ori remained in a state of maximum light about two years, then its brightness declined to the pre-outburst level (Kóspál et al. 2005). The optical and infrared light curves of V1647 Ori during the outburst are well studied and documented (Acosta-Pulido et al. 2007, Fedele et al. 2007, Aspin & Reipurth 2009, García-Alvarez et al. 2011). During the outburst V1647 Ori exhibited a strong emission spectrum in the optical and near-IR, typical for eruptive PMS stars of EXor type (Herbig 2008). However, the spectral structure in the infrared and the relatively long outburst give some reasons to classify the star as a FUor (Aspin et al. 2008).

A second outburst of the star was registered in 2008, when its brightness increased again to the level of the first eruption (Itagaki et al. 2008, Kun 2008). The optical and infrared follow-up observations show that the star and the surrounding nebula appear photometrically and morphologically similar to the first outburst (Aspin et al. 2009). Only a few papers publishing data from optical and infrared photometric observations during the second outburst have appeared until now (Kaurav et al. 2010, García-Alvarez et al. 2011, Aspin 2011). During both outbursts V1647 Ori showed a strong emission H α line with blueshifted absorption (P Cygni profile) while in the time between the outburst the H α line weakened and the blueshifted component disappeared (Aspin & Reipurth 2009, Aspin 2011). A correlation between the X-ray luminosity and $I_{\rm C}$ magnitude during the two outbursts were found by Teets et al. (2011).

The present paper is a continuation of our photometric study of the star during the first outburst (Semkov 2004, 2006). We present new $VR_{\rm C}I_{\rm C}$ photometric data of V1647 Ori in the period November 2008 – April 2012. A part of our data (from 2008 Nov 20 till 2010 Aug 20) are presented in Fig. 1 of García-Alvarez et al. (2011). Our data were obtained in two observatories with three telescopes: the 2-m RCC and the 50/70-cm Schmidt telescopes of the National Astronomical Observatory Rozhen (Bulgaria) and the 1.3-m RC telescope of the Skinakas Observatory of the Institute of Astronomy, University of Crete (Greece). The technical parameters and chip specifications of the CCD cameras

Telescope	CCD type	Size	Pixel	Field	RON
			size $[\mu m]$		$[\mathrm{ADU/rms}]$
2-m RCC	VersArray 1300B	1340×1300	20	$5'.6 \times 5'.6$	2.8
1.3-m RC	ANDOR DZ436-BV	2048×2048	13.5	$9'.6 \times 9'.6$	5.3
50/70-cm Schmidt	STL-11000M	4008×2672	9	$72' \times 48'$	13
50/70-cm Schmidt	FLI PL16803	4096×4096	9	$74' \times 74'$	9

Table 1. CCD cameras and chip specifications

used are summarized in Table 1. All frames were taken through a standard Johnson–Cousins set of filters. Aperture photometry was performed using DAOPHOT routines.

The $VR_{\rm C}I_{\rm C}$ comparison sequence reported in Semkov (2006) was used as a reference. In order to minimize the light from the surrounding nebula, all frames were reduced using the same aperture of 2".5 radius and the background was taken between radii 20" and 25". The typical errors in the reported magnitudes are in the range 0".01-0".03 (I and R) and 0".02-0".05 (V) for observations made with 2-m RCC and 1.3-m RC telescopes and in the range 0".02-0".04 (I) and 0".02-0".06 (R) for observations made with the Schmidt telescope. The results from our CCD photometric observations are given in Table 2. The table contains date, the Julian date, the $I_{\rm C}$, $R_{\rm C}$ and V magnitudes. Fig. 1 shows the V, $R_{\rm C}$ and $I_{\rm C}$ light curves of V1647 Ori for the period of our photometric observations. Typical error bars for each filter are shown at the left.

Figure 1. $V, R_{\rm C}$ and $I_{\rm C}$ light curves of V1647 Ori

Table 2. Photometric observations of V1647 Ori

The long-term photometric study of V1647 Ori can be very useful to determine the type of the eruption: FUor or EXor. Our observations suggest that the second outburst of V1647 Ori persists for approximately four years. The photometric data show a continuous slight decrease in brightness during the period of observations. In the meantime the star becomes redder with decreasing of its brightness. Using a linear approximation for our data, we calculated the following values for the rates of decline: ~0.07 mag yr⁻¹ for I, ~0.11 mag yr⁻¹ for R and ~0.15 mag yr⁻¹ for V. Random fluctuations in brightness with amplitudes of few tenths of magnitude and timescales of some days were recorded during the first outburst (see Aspin & Reipurth 2009 and references therein). Such a short time scale variability in brightness is observed during the second outburst.

According to Aspin et al. (2009) the decrease in brightness of V1647 Ori over the period 2006–2008 was caused by reduction of the accretion rate and reformation of dust in the circumstellar environment of the star. Therefore, we observe the same outburst that has slowed down temporarily. Such interpretation of the observational results leads Aspin et al. (2009) to the hypothesis that V1647 Ori is a FUor object. Our data show similar photometric behavior of the star during both outbursts and also support the hypothesis of the FUor nature of V1647 Ori. On the other hand the spectrum of the star during the second outburst remains similar to the spectra of EXor objects (Aspin 2011). Therefore, during the second outburst V1647 Ori continues to show the photometric properties of a FUor and the spectral properties of an EXor.
